Summary

Understanding the universe's large-scale distribution of dark matter is a central objective in the era of precision cosmology. A key technique for the study of dark matter is weak gravitational lensing: a phenomenon where light from distant galaxies is sheared as it passes through the gravitational field of a massive object, like a galaxy cluster. This shear, which manifests as a slight (weak) distortion of shapes over thousands of galaxies, allows astrophysicists to infer the distribution of total matter, including both luminous and dark matter.

Obtaining a mass distribution from a catalog of galaxy shears requires an intermediate step. A common tool for this step is the mapping of convergence (κ), which quantifies how much a gravitational lens converges the light from distant galaxies, resulting in a magnification of their shapes. This value is directly proportional to the projected mass density, enabling easy visualization of the overall mass distribution. For a comprehensive review of weak gravitational lensing refer to (Umetsu, 2020).

The **Shear Mapping in Python (SMPy)** package provides a standardized, well-documented, and open-source solution for creating convergence maps from weak lensing galaxy shear measurements. `SMPy` was initially developed to support the Superpressure Balloon-borne Imaging Telescope (SuperBIT), a stratospheric, near-UV to near-IR observing platform which completed its 45-night observing run in spring 2023 with over 30 galaxy cluster observations (Gill et al., 2024), (Sirks et al., 2023). `SMPy` has since evolved into a general-purpose tool suitable for analyzing the weak lensing data from cosmological.

Statement of Need

The weak lensing community is served by publicly available mapping tools like `lenspack` and `jax-lensing` (Remy et al., 2022), each with their own strengths. `jax-lensing` excels at neural network-based approaches and deep learning methods, while `lenspack` has a well-documented module specifically for traditional mass-mapping implementations. While both tools are powerful, the steep learning curve of `jax-lensing` and the rigid architecture of `lenspack` motivated the development of `SMPy` as an accessible and extensible alternative.

Thus, `SMPy` addresses an outstanding need for the lensing community: an accessible, well-documented, and extensible tool to construct publication-quality mass maps from galaxy shear data. Built on standard scientific Python packages, it provides an easy entry point for researchers new to mass mapping. It offers specialized and unique features valuable for mass mapping, such as flexible coordinate system support (both celestial and pixel space) and comprehensive signal-to-noise analysis with multiple randomization techniques. Its modular architecture also enables future contributions of new mapping methods. An example convergence map, created from simulated SuperBIT galaxy cluster observations (McCleary et al., 2023), is shown in

Figure 1. SMPy is, to our knowledge, the first convergence mapping software to prioritize both accessibility and advanced features.

SMPy was built with the following design principles in mind:

1. **Accessibility:** SMPy is written entirely in Python and deliberately relies only on widely-used scientific Python packages (numpy, scipy, pandas, astropy, matplotlib, and pyyaml). This choice of standard dependencies ensures that users can easily install the packages without complex dependency chains, and that the codebase is maintainable and familiar to the scientific Python community.
2. **Extensibility:** SMPy is built with a modular architecture that allows for easy implementation of new mass mapping techniques beyond the currently implemented Kaiser-Squires inversion algorithm (Kaiser & Squires, 1993). For example, we are planning to add aperture mass mapping (Leonard et al., 2012) and KS+ (Pires, 2020) algorithms to the codebase.
3. **Usability:** Creating convergence maps with SMPy requires minimal input—users need to only provide a catalog of galaxies with their associated shear components and coordinates. This straightforward input requirement makes the tool accessible to researchers at all levels. A flexible configuration system is integrated via a single YAML file that defines file paths, convergence map algorithm settings, plotting parameters, and more.
4. **Robustness:** SMPy is designed to be mathematically and algorithmically accurate, allowing the user to create convergence maps with any galaxy shear data. The coordinate system abstraction handles both celestial coordinates (with proper spherical geometry approximations) or pixel-based coordinates through a unified interface. To quantify the significance of the weak lensing detection, multiple noise realizations can be generated using either spatial shuffling (randomizing galaxy positions while preserving shear values) or orientation shuffling (randomizing shear orientations while preserving positions). These noise realizations are used to create a signal-to-noise map with the observed convergence.

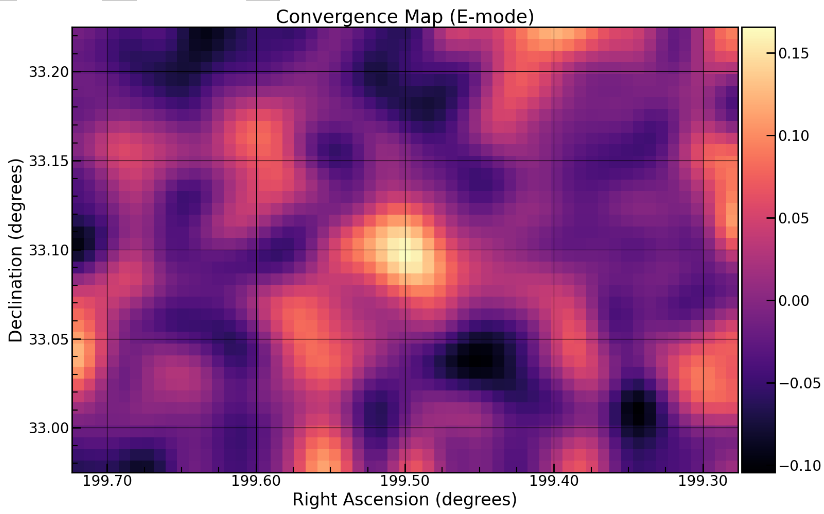

Figure 1: Example convergence map created with SMPy showing the mass distribution of a simulated galaxy cluster. The map was generated using the Kaiser-Squires inversion method on simulated weak lensing data from SuperBIT. The color scale represents the dimensionless surface mass density (convergence), with brighter regions indicating higher mass concentrations.

Software References

SMPy is written in Python 3.8+ and uses the following packages:

- `NumPy` (Harris et al., 2020)
- `SciPy` (Virtanen et al., 2020)
- `Pandas` (team, 2024)
- `Astropy` (Astropy Collaboration et al., 2022) (Astropy Collaboration et al., 2018) (Astropy Collaboration et al., 2013)
- `Matplotlib` (Hunter, 2007)
- `PyYAML` (Simonov, 2024)
